

LedgerFlow

Tokenized invoice financing for B2B cross-border trade on Solana

The Problem & Our Solution

Invoice factoring is slow and expensive for cross-border trade. LedgerFlow tokenizes invoices for instant stablecoin financing.

- Cross-border B2B invoice factoring is slow, opaque, and costly for SMEs.
- Banks take weeks to advance funds, blocking working capital for growing companies.
- LedgerFlow mints verified invoices as on-chain RWA tokens on Solana.
- A permissionless liquidity pool advances stablecoins instantly against those tokens.
- Investors earn yield backed by real receivables, not speculation.

How It Works

From invoice upload to instant stablecoin advance and automated repayment, all verified and settled on-chain.

- Enterprise uploads invoice; KYB/oracle partner verifies buyer and invoice authenticity.
- Verified invoice is minted as an RWA token representing the receivable on Solana.
- Liquidity pool instantly advances USDC against the token at a risk-based rate.
- On invoice settlement, smart contracts auto-repay the pool and distribute yield to LPs.
- Anchor programs handle minting, lending, and repayment; a dashboard tracks status for both sides.

Built with

Solana, Anchor, Solana Program Library, USDC, Chainlink/Pyth oracle, Next.js, Supabase

Why Now & What's Next

Solana's stablecoin and RWA infrastructure is finally fast and cheap enough for real invoice settlement.

- Stablecoin rails and RWA tooling on Solana have matured for real-world settlement use cases.
- Enterprises face tighter bank credit, increasing demand for alternative working capital.
- Next: partner with a KYB/credit-scoring provider for invoice verification.
- Next: pilot with 5-10 SMEs in a specific trade corridor.
- Next: add a secondary market for trading invoice tokens.
